1.

Consider a directed graph with distinct and nonnegative edge lengths and a source vertex s. Fix a destination vertex t, and assume that the graph contains at least one s-t path. Which of the following statements are true? [Check all that apply.]

- [x] There is a shortest s-t path with no repeated vertices (i.e., a "simple" or "loopless" such path).

Correct

- [x] The shortest s-t path must include the minimum-length edge of G.

Un-selected is correct

- [x] The shortest (i.e., minimum-length) s-t path might have as many as $n - 1$ edges, where n is the number of vertices.

Correct

- [x] The shortest s-t path must exclude the maximum-length edge of G.

Un-selected is correct

Problem Set #2

Quiz, 5 questions

3.75/5 points (75%)

2.

Consider a directed graph G with a source vertex s, a destination t, and nonnegative edge lengths. Under what conditions is the shortest s-t path guaranteed to be unique?

- When all edge lengths are distinct positive integers.
- None of the other options are correct.
- When all edges lengths are distinct positive integers and the graph G contains no directed cycles.
- When all edge lengths are distinct powers of 2.

Correct

Two sums of distinct powers of two cannot be the same (imagine the numbers are written in binary).

---

0 / 1 point

3.

Consider a directed graph $G = (V, E)$ and a source vertex s with the following properties: edges that leave the source vertex s have arbitrary (possibly negative) lengths; all other edge lengths are nonnegative; and there are no edges from any other vertex to the source s. Does Dijkstra's shortest-path algorithm correctly compute shortest-path distances (from s) in this graph?

- Never
- Only if we add the assumption that G contains no directed cycles with negative total weight.

This should not be selected

The hypotheses in the problem statement already imply that there is no such cycle,

- Maybe, maybe not (depends on the graph)
- Always

---

4.

Consider a directed graph G and a source vertex s. Suppose G has some negative edge lengths but no negative cycles, meaning G does not have a directed cycle in which the sum of the edge lengths is negative. Suppose you run Dijkstra's algorithm on G (with source s). Which of the following statements are true? [Check all that apply.]

Dijkstra's algorithm always terminates, but in some cases the paths it computes will not be the shortest paths from s to all other vertices.

Problem Set #2

3.75/5 points (75%)

Quiz, 5 questions

Correct

Nonnegativity of the edge lengths was used in the correctness proof for Dijkstra's algorithm; with negative edge lengths, the algorithm is no longer correct in general.

- [x] Dijkstra's algorithm always terminates, and in some cases the paths it computes will be the correct shortest paths from s to all other vertices.

Correct

See Question 3.

- [x] Dijkstra's algorithm might loop forever.

Un-selected is correct

- [x] It's impossible to run Dijkstra's algorithm on a graph with negative edge lengths.

Un-selected is correct

0.75 / 1 point

5.

Consider a directed graph G and a source vertex s. Suppose G contains a negative cycle (a directed cycle in which the sum of the edge lengths is negative) and also a path from s to this cycle. Suppose you run Dijkstra's algorithm on G (with source s). Which of the following statements are true? [Check all that apply.]

- [x] Dijkstra's algorithm always terminates, and in some cases the paths it computes will be the correct shortest paths from s to all other vertices.

This should not be selected

When there is negative cycle reachable from s, there is no shortest path from s from any vertex on cycle (every path can be made shorter by going around the cycle an additional time).

- [x] It's impossible to run Dijkstra's algorithm on a graph with a negative cycle.

Un-selected is correct

- [x] Dijkstra's algorithm might loop forever.

Un-selected is correct
